Reason for carpal tunnel syndrome

Pressure on the median nerve, the nerve that runs down the center of the arm and into the hand, can trigger carpal tunnel syndrome, a condition that causes pain, numbness, tingling, and reduced function. People using repetitive hand movements, such as computer operators, hairstylists, and massage therapists, are at a greater risk for developing this disorder. Pregnant women are also highly susceptible. Wrist splints and exercises can ease symptoms of minor carpal tunnel, though advanced cases may require surgery. 1. Pins and Needles The tingling sensation known as pins and needles often develops when an extremity is kept in an awkward position for an extended time, causing blood flow to become interrupted or a nerve to be compressed. People with carpal tunnel syndrome often experience a more intense and unpleasant version of this sensation. Usually, it only affects the thumb and first two fingers, but it can also spread to other areas of the hand and arm. The patients are trembling and becoming insensitive. The nerves in extremities are compressed, causing such feelings of discomfort. Many people put their hands under the body while having a sleep. Such position may lead to similar sensations as well, but they feel a bit different, and at least there are some good reasons for tingling. In the case of carpal tunnel syndrome, the pain lasts for a while. It hurts when you have a carpal tunnel syndrome. The patients feel like they are pierced with knives. Since the initial phases of illness, the pains are quite disturbing. The research studies showed this type of pain usually occurs in extremities, especially every part of the hands. It can go up to the shoulders and neck. Many pain patterns typical for the carpal tunnel syndrome remain unobserved. The suffering which occurs at night time while sleeping. It awakens many patients at night, making them almost cry. Unlike numbness, this pain cannot be ignored. Even if a person falls asleep without any obstacles, he or she may still wake up at some point in time, experiencing this awful sensation. Most of the time, the pain takes place in the limbs, especially hands. This syndrome negatively impacts common sleep patterns. Page 2 People with carpal tunnel syndrome may stop sensing their fingertips for a while. It lasts more than a usual numbness and makes most patients worried. Except for being ‘pierced by thousand knives,’ the patient loses connections with some parts of his body. It makes it difficult to move: eat, walk, write, etc. The most severe situations occur when the patient’s numbness achieves the peak: even the needles are not sensed anymore. Immobility and rigidity when a patient wakes up. The extremities can be more rigid than they usually are. Patient’s hands suffer most of all. Other people feel less discomfort after sleep. People with carpal tunnel syndrome find it hard to clench a toothbrush while cleaning their teeth. It is the result of the decrease in the general range of movement. The level of bending the hand can be impacted. Tumefaction is another widespread symptom of carpal tunnel syndrome. This term means that the limbs, especially upper extremities, turn swollen. It is hard to detect the reasons for the hands to become this way. From time to time, the patients experience a light tumor above the wrist. It feels like the hands are going numb. As a result, such people feel their extremities are swollen when they are not. Page 3 The muscle strength is gone. The hands stop feeling their power any longer. With the growing rigidity and loss of mobility, the patients also start experiencing regular pain in the area of hands. Pollex is the first place to face this problem. In the end, it becomes hard to do activities that involve the usage of the thumbs. Such immobility causes a lot of discomforts. People with carpal tunnel syndrome demonstrate reactions to any fluctuations on wrists. It becomes more difficult to put their hands in another position or conduct other daily activities in which these extremities are involved. Most often, this phenomenon is noticed at the initial stages. Do not leave symptoms like that without attention and corresponding health care as it would become almost impossible to move hands later. Burning sensation, irritation, and inflammation. Tingling is not the only problem so far: people who suffer from this disorder complain of the burning hands. No matter whether the patient decides to take a nap at night or day time, the burning sensation may be an obstacle. If the hand remains without any movement for some time, it may be burning too. Most of the time, the area around thumb and other fingers hurts. It happens because of the pressure on the median nerve. Hands many times turn itchy. The pollex and neighboring couple of fingers are attacked. The patient also feels his hands are going numb, which makes the situation worse. These two are the most typical symptoms of this health issue. The hand’s median nerve is guilty for this symptom as it is being pressed. Itching may be elusive, but it’s still impossible to ignore it and the discomfort it causes. Carpal tunnel syndrome is the result of swelling and inflammation in the carpal tunnel, a narrow channel between bones and ligaments within the wrist through which a major nerve passes. Called the median nerve, this nerve and its branches provide feeling to the thumb, index finger, long finger, and half of the ring finger. Additionally, it provides strength to the thumb and portions of the index and long fingers. When the space in the carpal tunnel decreases, the median nerve becomes squeezed, and a person may feel numbness and/or tingling and eventually weakness in the thumb and associated fingers. Facebook Twitter Linkedin Pinterest Carpal tunnel syndrome is when the median nerve is compressed as it passes through the carpal tunnel. The carpal tunnel is an opening in your wrist that is formed by the carpal bones on the bottom of the wrist and the transverse carpal ligament across the top of the wrist. The median nerve provides sensory and motor functions to the thumb and 3 middle fingers. If it gets compressed or irritated, you may have symptoms. Carpal tunnel release is one of the most common hand conditions requiring surgery. Symptoms may include tingling, pain, numbness or weakness in the thumb through ring fingers of the affected hand. Women get carpal tunnel syndrome three times more often than men. Carpal tunnel syndrome is a progressive condition that can worsen without proper care. Symptoms of carpal tunnel syndrome often occur during pregnancy and can be alleviated with nonsurgical treatments. Symptoms often improve after delivery, but such patients are at higher risk of developing carpal tunnel syndrome later in life. Most cases of carpal tunnel syndrome have no specific cause, although any or all of the following may be a contributing factor: Frequent, repetitive, small movements with the hands (such as with typing or using a keyboard) Frequent, repetitive, grasping movements with the hands (such as with sports and certain physical activities) Joint or bone disease (for example, arthritis, osteoarthritis, or rheumatoid arthritis) Hormonal or metabolic changes (for example, menopause, pregnancy, or thyroid imbalance) Changes in blood sugar levels (may be seen with type 2 diabetes) Other conditions or injuries of the wrist (for example, strain, sprain, dislocation, break, or swelling and inflammation) Family history of carpal tunnel syndrome What are the symptoms of carpal tunnel syndrome? These are the most common symptoms: Weakness when gripping objects with one or both hands Pain or numbness in one or both hands "Pins and needles" feeling in the fingers Swollen feeling in the fingers, especially the thumb and the index and middle fingers Pain or numbness that is worse at night, interrupting sleep The symptoms of carpal tunnel syndrome may be similar to other medical conditions or problems. Always see your health care provider for a diagnosis. (music) >> My name is Sophie Strike and I'm one of the hand and upper extremities surgeon at Johns Hopkins. I see patients with problems of the hand and upper extremity as well as patients who have tumors as I have a specialty in Orthopaedic Oncology.(music) Carpal tunnel syndrome is actually a compression of one of the large nerves of your arm at the level of the wrist and this can cause numbness, tingling, a burning pain or weakness of your fingers as this nerve controls some of the motion of your hand.(music) Often, carpal tunnel syndrome can be diagnosed with our clinical examination alone. If the diagnosis is not clear, we may refer patients to have a nerve conduction study as well.(music) The treatments for carpal tunnel syndrome range from non-invasive treatments such as splinting or hand therapy to work on ergonomics and nerve gliding exercises to injections which may also provide diagnostic information or, for persistent or severe cases, patients may require surgery.(music) (muffled speaking) For patients who have long-term symptoms, numbness that does not go away or start to have motor weakness in their hand, those are patients that we are more aggressive with pursuing surgery.(music) Often, the procedure can be done with light sedation and local anesthesia only so patients usually do not require full general anesthesia. After the procedure, they’ll have a soft dressing in place and can go home the same day. Your fingers are free to move and you may have some soreness in your wrist but, generally, patients get back to regular activities after about two to four weeks.(music) The long-term prognosis for mild cases is usually a near-full recovery within the first six months. Patients who have long-standing or severe symptoms may require a longer period of time and may not get back a hundred percent of their function that they had before. It can recur although we often see this 10, 15 years down the line and that can be treated if it comes up.(music) Your provider will check your medical history and give you a physical exam. He or she may recommend that you have electrodiagnostic tests on your nerves. These tests are the best way to diagnose carpal tunnel syndrome. Electrodiagnostic tests stimulate the muscles and nerves in your hand to see how well they work. Treatment of carpal tunnel syndrome Your health care provider will figure out the best treatment for you based on: Your age Your overall health and medical history How bad your wrist is right now How well you tolerate specific medications, procedures, or therapies How bad the disease is expected to get Your opinion or preference Treatment may include: Splinting your hand. This helps keep your wrist from moving. It also eases the compression of the nerves inside the tunnel. Anti-inflammatory medication. These may be oral or injected into the carpal tunnel space. These reduce the swelling. Surgery. This eases compression on the nerves in the carpal tunnel. Worksite changes. Changing position of your computer keyboard or making other ergonomic changes can help ease symptoms. Exercise. Stretching and strengthening exercises can be helpful in people whose symptoms have gotten better. These exercises may be supervised by a physical or occupational therapist. Surgery for carpal tunnel syndrome Surgery for carpal tunnel syndrome is usually done as an outpatient. Two types of carpal tunnel surgery are done: open surgery and endoscopic surgery. You may have local or general anesthesia, or both, for either surgery. During open surgery, the surgeon cuts open your wrist. The tissue that is pressing on the nerves is cut. This relieves the pressure on the nerve. During endoscopic surgery, the surgeon puts a long, thin rod through a tiny cut on the wrist. The rod, or scope, contains a camera and a light. The scope lets the surgeon to see inside your wrist. He or she cuts the tissue using tiny surgical tools. After the surgery, your hand and wrist are wrapped and put into a splint. This will help to keep you from moving your wrist during your recovery. You will need to wear the splint for a week or two. You will probably have some pain after your surgery. It's usually controlled with pain medication taken by mouth. You may also be told to sleep with your hand elevated to help ease swelling. Recovery from carpal tunnel surgery is different for each person. If your nerve has been compressed for a long time, recovery may take longer. You will be encouraged to move your fingers and wrist a few days after surgery to help prevent stiffness. You may need to adjust your work or home activities while you recover. Talk with your health care provider about what you need to change. Medically reviewed by William Morrison, M.D. — Written by Yvette Brazier on January 22, 2018SymptomsTreatmentDiagnosisExercisesCausesPreventionCarpal tunnel syndrome is a painful, progressive condition that occurs when the median nerve in the wrist is compressed.Also known as median nerve entrapment or median nerve compression, it may happen when a nerve swells, the tendons become inflamed, or something causes swelling in the carpal tunnel.Symptoms include tingling, burning, or itching and numbness in the palm of the hand and the fingers, especially the thumb and index finger.The National Institute of Neurological Disorders and Stroke (NINDS), describe carpal tunnel syndrome (CTS) as the “most common and widely known of the entrapment neuropathies in which the body’s peripheral nerves are compressed or traumatized.”CTS affects between 3 percent and 6 percent of adults in the United States. It normally develops between the ages of 45 and 64 years, and the prevalence increases with age. It can appear in one or both wrists. It is more common in women than in men.Without treatment, CTS can have a negative impact on a person’s quality of life. Eventually, the median nerve can become severely damaged, and there may be permanent numbness in the fingers and permanent weakness in the muscles that are innervated by the median nerve.It is often linked to computer use, but reports date back to the 1800s. It was familiar to orthopedic surgeons since before the widespread use of computers.Share on PinterestCarpal tunnel syndrome causes discomfort in the hand and up into the forearm.Symptoms tend to develop gradually over time.The first symptoms often appear during the night, or on waking up in the morning. Patients may feel the need to “shake out” their hands when they wake up. The discomfort may wake them repeatedly during the night.The three main symptoms associated with CTS are:These symptoms occur in the thumb and the two fingers next to it, as well as half of the ring finger. They may extend to the rest of the hand and into the forearm.As the condition progresses, symptoms may persist during the day. The person may lose grip strength and find it harder to form a fist or grasp small objects. Opening a bottle of soda, doing up buttons, or typing on a keyboard can become a challenge.If left untreated, the muscles at the base of the thumb may wither away, and the person may no longer be able to tell hot from cold with the thumb and finger.Symptoms tend to emerge or get worse after using the affected hand. The sensation of tingling, burning, and pain may worsen if the arm or hand has been in the same position for a long time.Treatment aims to relieve symptoms and slow the progression of CTS by reducing pressure on the median nerve.People with mild symptoms may find their condition improves without treatment within a few months, especially if they are aged 30 years or under or if CTS occurs during pregnancy.Self-help tipsThe following may help reduce discomfort:Resting the hand and wrist: The more rest the hand and wrist get, the greater the chance of relieving the symptoms.Cold compress: Placing an ice pack on the wrist may help when the problem flares up, but ice should not be applied ice directly onto the skin.Controlling the triggers: If CTS stems from repetitive hand movements, the person should take breaks so the hand and wrist have time to rest and recover.Occupational therapy: A therapist can teach a person how to repetitive tasks differently.Wrist splints: These keep the wrist in the same position and prevent it from bending. They can be worn during sleep, but also during the day if they do not interfere with daily activities. Wrist splints are available over the counter at pharmacies. A doctor or pharmacist can advise about the best one to choose.Most patients with mild symptoms who follow these strategies will notice an improvement within 4 weeks.MedicationsThe doctor may recommend corticosteroid injections to reduce inflammation. These are normally applied by injection, directly into the carpal tunnel. Tablets are available, but they are usually less effective. At first, the pain may increase, but it should start to reduce after 2 days. If the response is good, but symptoms return after a few months, another dose may be recommended. However, continued use of corticosteroids is not advisable, as there can be long-term adverse effects.Non-steroidal anti-inflammatory drugs (NSAIDs), such as aspirin or ibuprofen, may help relieve short-term pain. These may only help if the CTS is due to an underlying inflammatory condition, rather than repetitive use.Other treatments that may help include exercises and botox injections.A study published in the journal Clinical Rehabilitation found “strong evidence on efficacy of local and oral steroids; moderate evidence that vitamin B6 is ineffective and splints are effective and limited or conflicting evidence that NSAIDs, diuretics, yoga, laser, and ultrasound are effective, whereas exercise therapy and botulinum toxin B injection are ineffective.”SurgeryIn severe cases, where treatments have not been effective, and symptoms have lasted at least 6 months, surgery may be appropriate.Carpal tunnel release surgery, also called carpal tunnel decompression, is an outpatient procedure. It does not require an overnight stay in the hospital.Surgery involves cutting the carpal ligament, which is the roof of the carpal tunnel, to reduce pressure on the median nerve.The Cleveland Clinic estimates that surgery for CTS has a success rate of over 90 percent, and it is rare for the problem to return.As with any surgery, there is always a risk of complications, including infection, post-operative bleeding, nerve injury, and scarring.Self-tests for CTS include tapping the wrist lightly to see if this produces a tingling sensation or numbness in the fingers.Another test is to flex the wrist or hold it above the head for a minute. If there is pain, numbness, or tingling, it may mean that CTS is present.However, these tests are not conclusive.A primary care physician can usually diagnose CTS after asking about symptoms and examining the hand and wrist for signs of weakness in the muscles around the thumb. They will also assess how well the person can use the hand and wrist.A number of tests can indicate if a person is likely to have CTS.Tinel’s test, or Tinel’s sign: The doctor taps the median nerve at the wrist lightly to see whether the patient feels numbness or tingling in one or more fingers.Phalen’s test for wrist-flexion: The patient presses the backs of the hands against each other so that the wrist is bent. If tingling or numbness occurs within one minute, there may be damage to the median nerve.Nerve conduction study: Electrodes are placed on the hand and wrist. Small electric shocks are applied. The test measures how quickly the nerves transmit the impulses to the muscles.Electromyography: A fine needle is inserted into the muscle. Electrical activity on a screen can reveal whether there is any median nerve damage, and if so, how severe it is.Blood tests: Blood tests can detect an underlying condition that can be related to carpal tunnel syndrome, including hypothyroidism, rheumatoid, arthritis, or diabetes.Imaging scans: An x-ray can show whether there is a fracture or some other disorder, such as rheumatoid arthritis. An ultrasound scan can check the structure of the median nerve. Studies have found that MRI scans are not useful in diagnosing carpal tunnel syndrome.Here are two exercises that may help relieve the discomfort of CTS:1. Make a fist, with the back of the hand facing down. Slide the fingers up until they are pointing straight up toward the ceiling. Repeat five to 10 times.2. Make a fist. Open your hand and spread out the fingers, stretching them as far as possible. Repeat five to 10 times.However, it is unclear whether exercises really have any benefit.The carpal tunnel, also known as the carpal canal, is a narrow, rigid passageway of bones and ligaments at the base of the hand. The median nerve and tendons are also in the carpal tunnel.The carpal tunnel can sometimes narrow because the tendons become irritated and inflamed, or because some other swelling puts pressure on the median nerve.Sensations to the palm, the thumb, and three other fingers are controlled by the median nerve. The median nerve also controls the muscle that brings the thumb across the palm to touch the little finger. It does not control the little finger.Pressure on this nerve can lead to pain, numbness, and weakness in the hand and wrist, and this may cause pain to radiate up the arm and even to the shoulder.CTS can develop for various reasons. However, it is more likely if the person frequently uses extremes of wrist motion, if they are exposed to vibration, and if they repeatedly use their fingers, for example when typing.Sometimes, there is no clear cause.The most common causes are thought to be:repetitive maneuversrepeated use of vibrating hand toolswork stressspregnancy, for example, because of edema, or fluid retentioninflammatory, degenerative, and rheumatoid arthritishypothyroidism, or an underactive thyroiddiabetestrauma, such as dislocation or fracture of the wriststructural problems in the wrist jointlesions in the wrista cyst or tumor in the carpal tunnelan overactive pituitary glandany kind of swelling or inflammation around the tendonsResearch and possible risk factorsResearchers have found that a previous wrist fracture and the use of insulin, metformin, and sulphonylureas are associated with a higher chance of CTS. Smoking, hormone replacement therapy (HRT), the combined oral contraceptive pill, and oral corticosteroids did not appear to be not linked to a higher risk of CTS.One study has suggested that obesity, combined with a square-shaped wrist shape, may increase the likelihood of CTS developing. However, the team concluded that obesity was probably not the cause, because when participants with obesity lost weight, they continued to have CTS.The same team concluded in other research that the age of women at the menopause might be a factor, and that pregnancy-related hormones may increase the risk of CTS in women at the time of the menopause.Postmenopausal women who use aromatase inhibitor drugs for breast cancer often experience CTS.Apart from work-related factors, the main risk for CTS is inflammatory arthritis, but hypothyroidism and diabetes also appear to increase the chance of developing it, according to research published in the Journal of General Internal Medicine.The National Institute of Neurological Disorders and Stroke (NINDS) says that CTS is three times more likely to occur among people working in assembly operations than in data-entry personnel.The Canadian Centre for Occupational Health and Safety (CCOHS) list the following occupations as risk factors for CTS:Share on PinterestCTS is linked to repetitive hand movements, but there is no evidence to suggest that computer use is a significant factor.farmers, and specifically those milking cowsworkers using air-power hand toolsassembly-line workers handling objects on the conveyor beltcheck-out cashiers using laser scannersfactory, farm, or mechanical workers who wear tight glovesgardeners weeding by handlocksmiths, turning keysmechanics, using screwdrivers and pushing down ratchetsmusicians using a bow for a stringed instrumentoffice workers using mouse and keyboardpainters who repeatedly use a spray gunpoultry or meat processing workers who are deboning and cuttingstablehands, painters, and carpenters who press tools into the palmRepetitive movements from activities such as knitting can also increase the risk.Measures to reduce the risk of developing CTS include:not gripping too hard when performing manual tasksnot overbending the wrist, for example, all the way down or upsleeping and working with the wrists straightavoiding repeated flexing and extending of the wristsmaintaining correct posture to prevent putting undue strain on the wrist and handsredesigning the workstation to reduce unnatural and awkward wrist positionsresting and taking frequent breaks when performing routine tasks to protect against the long-term effectskeeping the hands warm by wearing gloves in a cold environment, as having cold hands can increase the risk of developing CTStreating any underlying conditions, for example, establishing good glucose control to help prevent the complications of diabetesAccording to the National Library of Medicine, there is no evidence that using a computer increases the risk of CTS, but ergonomic keyboards with an elevated and curved keyboard may reduce strain by helping to keep the hands in a neutral position.Some people recommend hand movement exercises, including yoga, and massages, but research has not confirmed that these are effective.
