Every element which is smaller than the pivot element is placed in the left list and every element which is larger is placed in the right list. The worst-case occurs when an array is reverse sorted.Best Case Time Complexity:O(n). The time complexity of the binary search is O(N) which is a marked improvement on the O(N) time complexity of Linear Search. This brings us to the end of this ‘Data Structures and Algorithms in Java’ article. You can think of it as improved version f selection sort, where it divides its input into a sorted and an unsorted region, and it iteratively shrinks the unsorted region by extracting the largest element and moving that to the sorted region. With this, we have completed the first part of’ this ‘Data Structures and Algorithms in Java’ article. To store that key/value pair, you can use a simple array like a data structure where keys (integers) can be used directly as an index to store data values. It is very simple and more effective on smaller data sets. Listed below are properties of a queue: Often referred to as the first-in-first-out list Supports two most fundamental methods enqueue(e): Insert element e, at the rear of the queue dequeue(): Remove and return the element from the front of the queue Queues are used in the asynchronous transfer of data between two processes, CPU scheduling, Disk Scheduling and other situations where resources are shared among multiple users and served on first come first server basis. It divides the input collection into equal halves and the item is compared with the middle element of the list. The inner loop finds the next smallest value and the outer loop places that value into its proper location. Here’s pseudocode representing Quicksort Algorithm.QuickSort(A as array, low as int, high as int){ if (low < high){ pivot_location = Partition(A,low,high) Quicksort(A,low, pivot_location) Quicksort(A, pivot_location + 1, high) } } Partition(A as array, low as int, high as int){ pivot = A[low] left = low for i = low + 1 to high{ if (A[i] < pivot) then{ swap(A[i], A[left + 1]) left = left + 1 } } swap(pivot,A[left]) return (left)} In the above pseudocode, partition() function performs partition operation and Quicksort() function repeatedly calls partition function for each smaller list generated. Objects can be inserted into a stack at any point of time, but only the most recently inserted (that is, “last”) object can be removed at any time. Recursively sort each of the smaller lists. The integer N defines the capacity of the array. If an element is equal to the pivot element then it can go in any list. a[n] l1 = mergesort(l1) l2 = mergesort(l2) return merge(l1, l2) end procedure procedure merge(a as array, b as array) var c as array while (a and b have elements) if (a[0] > b[0]) add b[0] to the end of c remove b[0] from b else add a[0] to the end of c remove a[0] from a end if end while while (a has elements) add a[0] to the end of c remove a[0] from a end while while (b has elements) add b[0] to the end of c remove b[0] from b end while return c end procedure mergesort() function divides the list into two, calls mergesort() on these lists separately and then combines them by sending them as parameters to merge() function. Else, we continue looking for the element by dividing and selecting the appropriate partition of the array, based on if the target element is smaller or bigger than the middle element.Here’s pseudocode representing Binary Search in Java:Procedure binary_search a; sorted array n; size of array x; value to be searched lowerBound = 1 upperBound = n while x not found if upperBound < lowerBound EXIT: x does not exists. It is stable and in-place sorting technique.Here’s pseudocode representing Insertion Sort Algorithm (ascending sort context).a[] is an array of size N begin InsertionSort(a[]) for i = 1 to N key = a[i] j = i - 1 while (j >= 0 and a[j] > key0 a[j+1] = x[j] j = j - 1 end while a[j+1] = key end for end InsertionSort As you can understand from the code, the insertion sort algorithm removes one element from the input data, finds the location it belongs within the sorted list and inserts it there. Listed below are the topics discussed in this article:Data Structures in JavaA data structure is a way of storing and organizing data in a computer so that it can be used efficiently. If the element is found, the search ends there. Search algorithms are algorithms for finding an item with specified properties among a collection of items. Follows heap property: A Binary Heap is either a Min-Heap or a Max-Heap. Divide the lists into two lists based on this pivot element. Size of an array must be provided before storing data. A hash table is a data structure that implements a dictionary ADT, a structure that can map unique keys to values.In general, a hash table has two major components: Bucket Array: A bucket array for a hash table is an array A of size N, where each cell of A is thought of as a “bucket”, that is, a collection of key-value pairs. They are represented in two ways: Flowcharts – It is a visual representation of an algorithm’s control flow Pseudocode – It is a textual representation of an algorithm that approximates the final source codeNote: The performance of the algorithm is measured based on time complexity and space complexity. a[n/2] var l2 as array = a[n/2+1] ... Next up in this ‘Data Structures and Algorithms in Java’ article, we have hierarchical data structures.Hierarchical Data Structures in JavaBinary TreeBinary Tree is a hierarchical tree data structures in which each node has at most two children, which are referred to as the left child and the right child. Best case occurs when an array is already sorted.Selection Sort in JavaSelection sorting is a combination of both searching and sorting. This is called the partition operation. An algorithm is a sequence of instructions that describes a way of solving a specific problem in a finite period of time. Last updated on Jun 17,2021 29.8K Views If I had to pick the single most important topic in software development, it would be data structures and algorithms. The values are then stored in a data structure called a hash table. Hash Function: It is any function that maps each key k in our map to an integer in the range [0, N − 1], where N is the capacity of the bucket array for this table.When we put objects into a hashtable, it is possible that different objects might have the same hashcode. While it certainly is the simplest, it’s most definitely is not the most common, due to its inefficiency. But the problem is the algorithm needs one whole pass without any swap to know that the list is sorted.Worst and Average Case Time Complexity: O(n*n). It is the most commonly used search algorithms primarily due to its quick search time. The most commonly used orders are numerical order and lexicographical order. However, in cases where the keys are too large and cannot be used directly as an index, a technique called hashing is used.In hashing, the large keys are converted into small keys by using hash functions. This is called a collision. I have covered one of the most fundamental and important topics of Java. A linked list is similar.StacksStack, an abstract data structure, is a collection of objects that are inserted and removed according to the last-in-first-out (LIFO) principle. Selection sort never makes more than O(n) swaps and can be useful when the memory write is a costly operation.Time Complexity: O(n2) as there are two nested loops.Auxiliary Space: O(1).Insertion Sort in JavaInsertion Sort is a simple sorting algorithm which iterates through the list by consuming one input element at a time and builds the final sorted array. Each pass uses an inner loop to exchange data items such that the next smallest data item “bubbles” towards the beginning of the array. You can easily add another paperclip to the top or bottom. You can think of it as the fundamental tool available to every computer programmer. Bubble sort gets its name because it filters out the elements to the top of the array, like bubbles that float on water.Here’s pseudocode representing Bubble Sort Algorithm (ascending sort context).a[] is an array of size N begin BubbleSort(a[]) declare integer i, j for i = 0 to N - 1 for j = 0 to N - i - 1 if a[j] > a[j+1] then swap a[j], a[j+1] end if end for return a end BubbleSort This code orders a one-dimensional array of N data items into ascending order. Min Binary Heap: For every node in a heap, node’s value is lesser than or equal to values of the children Max Binary Heap: For every node in a heap, the node’s value is greater than or equal to values of the children Popular applications of binary heap include implementing efficient priority-queues, efficiently finding the k smallest (or largest) elements in

an array and many more.Hash TablesImagine that you have an object and you want to assign a key to it to make searching very easy. During the combination of the lists, the elements are inserted (or merged) at the right place in the list.Here’s pseudocode representing Merge Sort Algorithm.procedure MergeSort(a as array) if (n == 1) return a var l1 as array = a[0] ... set midPoint = lowerBound + (upperBound - lowerBound) / 2 if A[midPoint] < x set lowerBound = midPoint + 1 if A[midPoint] > x set upperBound = midPoint - 1 if A[midPoint] = x EXIT: x found at location midPoint end while end procedureThe search terminates when the upperBound (our pointer) goes past lowerBound (last element), which implies we have searched the whole array and the element is not present. It repeats until no input elements remain unsorted.Best Case: The best case is when input is an array that is already sorted. Moving on to the next set of algorithms in this ‘Data Structures and Algorithms’ article, let’s explore searching algorithms.Searching Algorithms in JavaSearching is one of the most common and frequently performed actions in regular business applications. Let’s explore two of the most commonly used searching algorithms.Linear Search Algorithm in JavaLinear search or sequential search is the simplest search algorithm. It picks an element as pivot and partitions the given array around that picked pivot. Steps to implement Quick sort: Pick a suitable “pivot point”. Similar to quicksort, merge sort divides the list of elements into two lists. While programming, we use data structures to store and organize data, and algorithms to manipulate the data in those structures. In the next part, we are going to learn about basic algorithms and how to use them in practical applications such as sorting and searching, divide and conquer, greedy algorithms, dynamic programming.Algorithms in JavaHistorically used as a tool for solving complex mathematical computations, algorithms are deeply connected with computer science, and with data structures in particular. Rather than use ten different variables for this task, we could use a single name for the entire group and use index numbers to refer to the high scores in that group.Linked ListA linked list is a linear data structure with the collection of multiple nodes, where each element stores its own data and a pointer to the location of the next element. The complexity of quicksort in the average case is Θ(n log(n)) and in the worst case is Θ(n2).Merge Sort in JavaMergesort is a fast, recursive, stable sort algorithm which also works by the divide and conquer principle. We are here to help you with every step on your journey, for becoming a besides this java interview questions, we come up with a curriculum which is designed for students and professionals who want to be a Java Developer. Got a question for us? The last link in a linked list points to null, indicating the end of the chain. To deal with collision, there are techniques like chaining and open addressing.So, these are some basic and most frequently used data structures in Java. In this ‘Data Structures and Algorithms’ article lets explore a few sorting algorithms.Bubble Sort in JavaBubble Sort, often referred to as sinking sort, is the simplest sorting algorithm. If the element is found, then the location of the item is returned otherwise the algorithm returns NULL.Here’s pseudocode representing Linear Search in Java: procedure linear_search (a[] , value) for i = 0 to n-1 if a[i] = value then print "Found " return i end if print "Not found" end for end linear_searchIt is a brute-force algorithm. All you have to do is to just disconnect the chain at the middle, add the new paperclip, then reconnect the other half. Finally, heapify the root of tree Repeat the above steps until the size of the heap is greater than 1Here’s pseudocode representing Heap Sort Algorithm.Heapsort(a as array) for (i = n / 2 - 1) to i >= 0 heapify(a, n, i); for i = n-1 to 0 swap(a[0], a[i]) heapify(a, i, 0); end for end for heapify(a as array, n as int, i as int) largest = i //Initialize largest as root int l eft = 2*i + 1; // left = 2*i + 1 int right = 2*i + 2; // right = 2*i + 2 if (left < n) and (a[left] > a[largest]) largest = left if (right < n) and (a[right] > a[largest]) largest = right if (largest != i) swap(a[i], A[largest]) Heapify(a, n, largest) end heapify Apart from these, there are other sorting algorithms which are not that well known such as, Introsort, Counting Sort, etc. These lists are sorted independently and then combined. This property of Binary Heap makes it suitable to be stored in an array. Mostly, the complexity of any algorithm is dependent on the problem and on the algorithm itself.Let’s explore the two major categories of algorithms in Java, which are: Sorting Algorithms in Java Searching Algorithms in JavaSorting Algorithms in JavaSorting algorithms are algorithms that put elements of a list in a certain order. It provides a means to manage large amounts of data efficiently. In this case insertion sort has a linear running time (i.e., Θ(n)).Worst Case: The simplest worst case input is an array sorted in reverse order.QuickSort in JavaQuicksort algorithm is a fast, recursive, non-stable sort algorithm which works by the divide and conquer principle. It involves sequential searching for an element in the given data structure until either the element is found or the end of the structure is reached. That is, elements can be inserted at any point of time, but only the element that has been in the queue the longest can be removed at any time. This article contains a detailed review of all the common data structures and algorithms in Java to allow readers to become well equipped. Each binary tree has the following groups of nodes: Root Node: It is the topmost node and often referred to as the main node because all other nodes can be reached from the root Left Sub-Tree, which is also a binary tree Right Sub-Tree, which is also a binary treeListed below are the properties of a binary tree: A binary tree can be traversed in two ways: Depth First Traversal: In-order (Left-Root-Right), Preorder (Root-Left-Right) and Postorder (Left-Right-Root) Breadth First Traversal: Level Order Traversal Time Complexity of Tree Traversal: O(n) The maximum number of nodes at level ‘l’ = 2l-1.Applications of binary trees include: Used in many search applications where data is constantly entering/leaving As a workflow for compositing digital images for visual effects Used in almost every high-bandwidth router for storing router-tables Also used in wireless networking and memory allocation Used in compression algorithms and many moreBinary HeapBinary Heap is a complete binary tree, which answers to the heap property. In simple terms it is a variation of a binary tree with the following properties: Heap is a complete binary tree: A tree is said to be complete if all its levels, except possibly the deepest, are complete. Steps to implement Quicksort(in increasing order): Build a max heap with the sorting array At this point, the largest item is stored at the root of the heap. Time Complexity of Linear search is O(N).Binary Search Algorithm in JavaBinary search, also known as logarithmic search, is a search algorithm that finds the position of a target value within an already sorted array. An element in a linked list is called a node. Unlike a stack, the queue is a collection of objects that are inserted and removed according to the first-in-first-out (FIFO) principle. Replace it with the last item of the heap and reduce the size of heap by 1. Now that you are aware of each of these, you can start implementing them in your Java programs. It’s even quick to insert one in the middle. An outer loop makes N-1 passes over the array. Listed below are properties of an array: Each element in an array is of the same data type and has the same size Elements of the array are stored at contiguous memory locations with the first element is starting at the smallest memory location Elements of the array can be randomly accessed The array data structure is not completely dynamicFor example, we may want a video game to keep track of the top ten scores for that game. And efficient data structures are key to designing efficient algorithms. In this ‘Data Structures and Algorithms in Java’ article, we are going to cover basic data structures such as: Linear Data Structures Linked List Stacks Queues Hierarchical Data Structures Binary Trees Heaps Hash Tables Let’s check out each of them.Linear Data Structures in JavaLinear data structures in Java are those whose elements are sequential and ordered in a way so that: there is only one first element and has only one next element, there is only one last element and has only one previous element, while all other elements have a next and a previous element.ArraysAn array is a linear data structure representing a group of similar elements, accessed by index. Hope you are clear with all that has been shared with you in this article.Make sure you practice as much as possible and revert your experience. Check out the Java Course Training by Edureka, a trusted online learning company with a network of more than 250,000 satisfied learners spread across the globe. It repeatedly steps through the list to be sorted, compares each pair of adjacent elements and swaps them if they are in the wrong order. The first node is called the head. The last node is called the tail.Types of Linked ListSingly Linked List (Uni-Directional)Doubly Linked List (Bi-Directional)Circular Linked ListHere’s a simple example: Imagine a linked list like a chain of paperclips that are linked together. The algorithm has a complexity of O(n log (n)) and has a wide range of applications.Heap Sort in JavaHeapsort is a comparison-based sorting algorithm Binary Heap data structure. Please mention it in the comments section of this ‘Data Structures and Algorithms in Java’ article and we will get back to you as soon as possible. The algorithm sorts an array by repeatedly finding the minimum element (considering ascending order) from the unsorted part and putting it at a proper position in the array.Here’s pseudocode representing Selection Sort Algorithm (ascending sort context).a[] is an array of size N begin SelectionSort(a[]) for i = 0 to n - 1 /* set current element as minimum*/ min = i /* find the minimum element */ for j = i+1 to n if list[j] < list[min] then min = j; end if end for /* swap the minimum element with the current element*/ if min != i then swap list[min], list[i] end if end for end SelectionSort As you can understand from the code, the number of times the sort passes through the array is one less than the number of items in the array. Listed below are properties of a stack: It is an orderd list in which insertion and deletion can be performed only at one end that is called the top Recursive data structure with a pointer to its top element Follows the last-in-first-out (LIFO) principle Supports two most fundamental methods push(e): Insert element e, to the top of the stack pop(): Remove and return the top element on the stack Practical examples of the stack include when reversing a word, to check the correctness of parentheses sequence, implementing back functionality in browsers and many more.QueuesQueues are also another type of abstract data structure.
