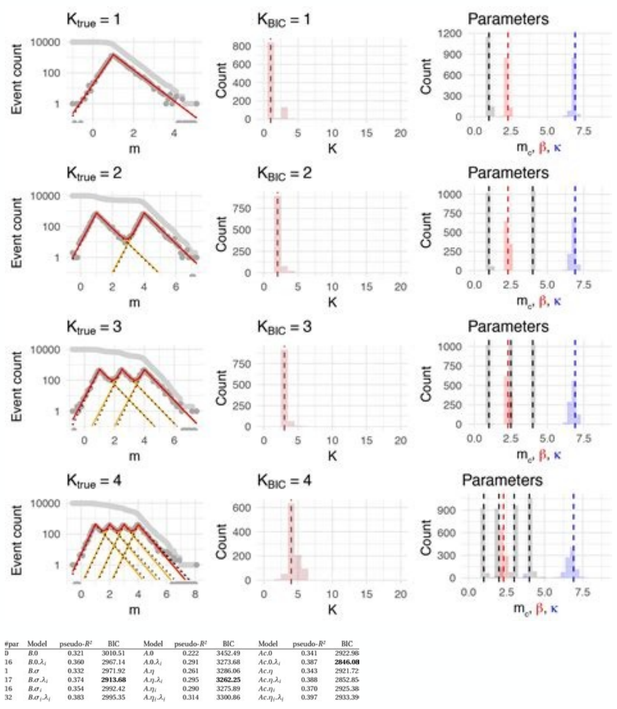
Bayesian Information Criterion (BIC) (2/3)

- In this work, we suggest using BIC as the splitting criterion of a cluster in order to decide whether a cluster should split or not.
- It measures the improvement of the cluster structure between a cluster and its two children clusters.
- We compute the BIC score of:
  - A cluster and of its
  - Two children clusters.



#par	Model	pseudo-R^2	BIC	Model	pseudo-R^2	BIC	Model	pseudo-R^2	BIC
0	$B.0$	0.321	3010.51	$A.0$	0.222	3432.49	$Ac.0$	0.341	2922.86

Definition

The BIC is formally defined as

$$\mathrm{BIC} = -2 \cdot \ln \hat{L} + k \cdot \ln(n).$$

where

n = the number of data points or . the number of observations, or equivalently, the sample size;
k = the number of free parameters to be estimated. If the model under consideration is a linear regression, k is the number of regressors, including the intercept;
^L = the maximized value of the likelihood function of the model

Bayesian information criterion (bic) (schwarz 1978).

Bayesian Statistics > The Bayesian Information Criterion (BIC) is an index used in Bayesian statistics to choose between two or more alternative models. The BIC is also known as the Schwarz information criterion (abrv. SIC) or the Schwarz-Bayesian information criteria. It was published in a 1978 paper by Gideon E. Schwarz, and is closely related to the Akaike information criterion (AIC) which was formally published in 1974. Definition of the Bayesian Information Criterion / Schwarz Criterion The Bayesian Information Criterion (BIC) is defined as k log(n)- 2log(L(θ)). Here n is the sample size; the number of observations or number of data points you are working with. k is the number of parameters which your model estimates, and θ is the set of all parameters. L(θ) represents the likelihood of the model tested, given your data, when evaluated at maximum likelihood values of θ. You could call this the likelihood of the model given everything aligned to their most favorable. Another way of understanding L(θ) is that it is the probability of obtaining the data which you have, supposing the model being tested was a given. Comparing Models Comparing models with the Bayesian information criterion simply involves calculating the BIC for each model. The model with the lowest BIC is considered the best, and can be written BIC* (or SIC* if you use that name and abbreviation). We can also calculate the Δ BIC; the difference between a particular model and the 'best' model with the lowest BIC, and use it as an argument against the other model. Δ BIC is just BICmodel – BIC*, where BIC* is the best model. If Δ BIC is less than 2, it is considered 'barely worth mentioning' as an argument either for the best theory or against the alternate one. The edge it gives our best model is too small to be significant. But if Δ BIC is between 2 and 6, one can say the evidence against the other model is positive; i.e. we have a good argument in favor of our 'best model'. If it's between 6 and 10, the evidence for the best model and against the weaker model is strong. A Δ BIC of greater than ten means the evidence favoring our best model vs the alternate is very strong indeed. Example Suppose you have a set of data with 50 observation points, and Model 1 estimates 3 parameters. Model 2 estimates 4 parameters. Let's say the log of your maximum likelihood for model 1 is a; and for model 2 it is 2a. Using the formula k log(n)- 2log(L(θ)): Calculating SIC on this data gives us: Model 1: 3log(50) – 2a = 5.1 – 2a Model 2: 4log(50) – 4a = 6.8 – 4a So ΔBIC is 1.7 – 2a. Since the evidence that the Bayesian Information Criterion gives us for model 1 will only be 'worth mentioning' if 1.7 – 2a > 2, we can only claim conclusive results if -2a > 0.3; that is to say, a < -0.15. Retrieved from jsessionid=A6726BA5AE1AD2A5AF007FFF78528249.f03t01?v=1&t=je8jr983&s=09eca6efc0573a238457d475d3ac909ec816a699 on March 1, 2018 Wasserman, Larry. STAT 705 Lecture Notes: Model Selection Retrieved from larry/=stat705/Lecture16.pdf on March 1, 2018 An index used as an aid in choosing between competing models. It is defined as -2Lm + mlnn where n is the sample size, Lm is the maximized log-likelihood of the model and m is the number of parameters in the model. The index takes into account both the statistical goodness of fit and the number of parameters that have to be estimated to achieve this particular degree of fit, by imposing a penalty for increasing the number of parameters. In statistics, the Schwarz criterion (also Schwarz information criterion (SIC) or Bayesian information criterion (BIC) or Schwarz-Bayesian information criterion) is an information criterion. Wikipedia (2005) "The Schwarz Criterion is a criterion for selecting among formal econometric models." About, Inc. (2006) "...the measure BIC = -2lnL + plnn. This form is derived from different points of view by Schwarz (1978), Akaike (1977), and Rissanen (1978)." Hjorth (1994) The problem of selecting one of a number of models of different dimensions is treated by finding its Bayes solution, and evaluating the leading terms of its asymptotic expansion. These terms are a valid large-sample criterion beyond the Bayesian context, since they do not depend on the a priori distribution. Download Citation Gideon Schwarz. "Estimating the Dimension of a Model." Ann. Statist. 6 (2) 461 - 464, March, 1978. First available in Project Euclid: 12 April 2007 Digital Object Identifier: 10.1214/aos/1176344136 Keywords: Akaike information criterion , asymptotics , dimension Rights: Copyright © 1978 Institute of Mathematical Statistics Criterion for model selection Part of a series onBayesian statistics Theory Admissible decision rule Bayesian efficiency Bayesian epistemology Bayesian probability Probability interpretations Bayes' theorem Bayes factor Bayesian inference Bayesian network Prior Posterior Likelihood Conjugate prior Posterior predictive Hyperparameter Hyperprior Principle of indifference Principle of maximum entropy Empirical Bayes method Cromwell's rule Bernstein–von Mises theorem Schwarz criterion Credible interval Maximum a posteriori estimation Radical probabilism Techniques Bayesian linear regression Bayesian estimator Approximate Bayesian computation Markov chain Monte Carlo Integrated nested Laplace approximations Mathematics portalvte In statistics, the Bayesian information criterion (BIC) or Schwarz information criterion (also SIC, SBC, SBIC) is a criterion for model selection among a finite set of models; models with lower BIC are generally preferred. It is based, in part, on the likelihood function and it is closely related to the Akaike information criterion (AIC). When fitting models, it is possible to increase the likelihood by adding parameters, but doing so may result in overfitting. Both BIC and AIC attempt to resolve this problem by introducing a penalty term for the number of parameters in the model; the penalty term is larger in BIC than in AIC.[1] The BIC was developed by Gideon E. Schwarz and published in a 1978 paper,[2] where he gave a Bayesian argument for adopting it. Definition The BIC is formally defined as[3][a] B I C = k ln ⁡ (n) − 2 ln ⁡ (L ^) . {\displaystyle \mathrm {BIC} =k\ln(n)-2\ln({\widehat {L}}).\ } where L ^ {\displaystyle {\hat {L}}} = the maximized value of the likelihood function of the model M {\displaystyle M} , i.e. L ^ = p (x | θ ^ , M) {\displaystyle {\hat {L}}=p(x\mid {\widehat {\theta }},M)} , where θ ^ {\displaystyle {\widehat {\theta }}} are the parameter values that maximize the likelihood function; x {\displaystyle x} = the observed data; n {\displaystyle n} = the number of data points in x {\displaystyle x} , the number of observations, or equivalently, the sample size; k {\displaystyle k} = the number of parameters estimated by the model. For example, in multiple linear regression, the estimated parameters are the intercept, the q {\displaystyle q} slope parameters, and the constant variance of the errors; thus, k = q + 2 {\displaystyle k=q+2} . Konishi and Kitagawa[5]:217 derive the BIC to approximate the distribution of the data, integrating out the parameters using Laplace's method, starting with the following model evidence: p (x | M) = ∫ p (x | θ , M) π (θ | M) d θ {\displaystyle p(x\mid M)=\int p(x\mid \theta ,M)\pi (\theta \mid M)\,d\theta } where π (θ | M) {\displaystyle \pi (\theta \mid M)} is the prior for θ {\displaystyle \theta } under model M {\displaystyle M} . The log-likelihood, ln ⁡ (p (x | θ , M)) {\displaystyle \ln(p(x\mid \theta ,M))} , is then expanded to a second order Taylor series about the MLE, θ ^ {\displaystyle {\widehat {\theta }}} , assuming it is twice differentiable as follows: ln ⁡ (p (x | θ , M)) = ln ⁡ (L ^) − 0.5 (θ − θ ^) ′ n I (θ) (θ − θ ^) + R (x , θ) , {\displaystyle \ln(p(x\mid \theta ,M))=\ln({\widehat {L}})-0.5(\theta -{\widehat {\theta }})'n{\mathcal {I}}(\theta)(\theta -{\widehat {\theta }})+R(x,\theta),} where I (θ) {\displaystyle {\mathcal {I}}(\theta)} is the average observed information per observation, and prime (′ {\displaystyle '}) denotes transpose of the vector (θ − θ ^) {\displaystyle (\theta -{\widehat {\theta }})} . To the extent that R (x , θ) {\displaystyle R(x,\theta)} is negligible and π (θ | M) {\displaystyle \pi (\theta \mid M)} is relatively linear near θ ^ {\displaystyle {\widehat {\theta }}} , we can integrate out θ {\displaystyle \theta } to get the following: p (x | M) ≈ L ^ (2 π / n) k / 2 | I (θ ^) | − 1 / 2 π (θ ^) {\displaystyle p(x\mid M)\approx {\hat {L}}(2\pi /n)^{k/2}{\mathcal {I}}({\widehat {\theta }})^{-1/2}\pi ({\widehat {\theta }})} As n {\displaystyle n} increases, we can ignore | I (θ ^) | {\displaystyle |{\mathcal {I}}({\widehat {\theta }})|} and π (θ ^) {\displaystyle \pi ({\widehat {\theta }})} as they are O (1) {\displaystyle O(1)} . Thus, p (x | M) = exp ⁡ { ln ⁡ L ^ − (k / 2) ln ⁡ (n) + O (1) } = exp ⁡ (− B I C / 2 + O (1)) , {\displaystyle p(x\mid M)=\exp\{\ln {\widehat {L}}-(k/2)\ln(n)+O(1)\}=\exp(-\mathrm {BIC} /2+O(1)),} where BIC is defined as above, and L ^ {\displaystyle {\widehat {L}}} either (a) is the Bayesian posterior mode or (b) uses the MLE and the prior π (θ | M) {\displaystyle \pi (\theta \mid M)} has nonzero slope at the MLE. Then the posterior p (M | x) ∝ p (x | M) p (M) ≈ exp ⁡ (− B I C / 2) p (M) {\displaystyle p(M\mid x)\propto p(x\mid M)p(M)\approx \exp(-\mathrm {BIC} /2)p(M)} Usage When picking from several models, ones with lower BIC values are generally preferred. The BIC is an increasing function of the error variance σ e 2 {\displaystyle \sigma _{e}^{2}} and an increasing function of k. That is, unexplained variation in the dependent variable and the number of explanatory variables increase the value of BIC. However, a lower BIC does not necessarily indicate one model is better than another. Because it involves approximations, the BIC is merely a heuristic. In particular, differences in BIC should never be treated like transformed Bayes factors. It is important to keep in mind that the BIC can be used to compare estimated models only when the numerical values of the dependent variable[b] are identical for all models being compared. The models being compared need not be nested, unlike the case when models are being compared using an F-test or a likelihood ratio test.[citation needed] Properties This section needs additional citations for verification. Please help improve this article by adding citations to reliable sources. Unsourced material may be challenged and removed. (November 2011) (Learn how and when to remove this template message) The BIC generally penalizes free parameters more strongly than the Akaike information criterion, though it depends on the size of n and relative magnitude of n and k. It is independent of the prior. It can measure the efficiency of the parameterized model in terms of predicting the data. It penalizes the complexity of the model where complexity refers to the number of parameters in the model. It is approximately equal to the minimum description length criterion but with negative sign. It can be used to choose the number of clusters according to the intrinsic complexity present in a particular dataset. It is closely related to other penalized likelihood criteria such as Deviance information criterion and the Akaike information criterion. Limitations The BIC suffers from two main limitations[6] the above approximation is only valid for sample size n {\displaystyle n} much larger than the number k {\displaystyle k} of parameters in the model. the BIC cannot handle complex collections of models as in the variable selection (or feature selection) problem in high-dimension.[6] Gaussian special case Under the assumption that the model errors or disturbances are independent and identically distributed according to a normal distribution and the boundary condition that the derivative of the log likelihood with respect to the true variance is zero, this becomes (up to an additive constant, which depends only on n and not on the model):[7] B I C = n ln ⁡ (σ e 2 ^) + k ln ⁡ (n) {\displaystyle \mathrm {BIC} =n\ln({\widehat {\sigma _{e}^{2}}})+k\ln(n)\ } where σ e 2 ^ {\displaystyle {\widehat {\sigma _{e}^{2}}}} is the error variance. The error variance in this case is defined as σ e 2 ^ = 1 n ∑ i = 1 n (x i − x i ^) 2 . {\displaystyle {\widehat {\sigma _{e}^{2}}}={\frac {1}{n}}\sum _{i=1}^{n}(x_{i}-{\widehat {x_{i}}})^{2}.} which is a biased estimator for the true variance. In terms of the residual sum of squares (RSS) the BIC is B I C = n ln ⁡ (R S S / n) + k ln ⁡ (n) {\displaystyle \mathrm {BIC} =n\ln(RSS/n)+k\ln(n)\ } When testing multiple linear models against a saturated model, the BIC can be rewritten in terms of the deviance χ 2 {\displaystyle \chi ^{2}} as:[8] B I C = χ 2 + k ln ⁡ (n) {\displaystyle \mathrm {BIC} =\chi ^{2}+k\ln(n)} where k {\displaystyle k} is the number of model parameters in the test. See also Akaike information criterion Bayes factor Bayesian model comparison Deviance information criterion Hannan–Quinn information criterion Jensen–Shannon divergence Kullback–Leibler divergence Minimum message length Notes ^ The AIC, AICc and BIC defined by Claeskens and Hjort[4] are the negatives of those defined in this article and in most other standard references. ^ A dependent variable is also called a response variable or an outcome variable. In mathematical statistics, the Fisher information (sometimes simply called information) is a way of measuring the amount of information that an observable random variable X carries about an unknown parameter θ of a distribution that models X.Formally, it is the variance of the score, or the expected value of the observed information.In Bayesian statistics, the asymptotic … Mar 10, 2018 · Bayesian Statistics >. The Bayesian Information Criterion (BIC) is an index used in Bayesian statistics to choose between two or more alternative models.. The BIC is also known as the Schwarz information criterion (abrv. SIC) or the Schwarz-Bayesian information criteria.It was published in a 1978 paper by Gideon E. Schwarz, and is closely related to the Akaike ... The criterion for selecting optimal k may be set using the parameter to this option, which should be one of AIC, BIC or tstat, AIC being the default. When testing down via AIC or BIC, the final lag order for the ADF equation is that which optimizes the chosen information criterion (Akaike or Schwarz Bayesian). En estadística, el criterio de información bayesiano (BIC) o el más general criterio de Schwarz (SBC también, SBIC) es un criterio para la selección de modelos entre un conjunto finito de modelos. Se basa, en parte, de la función de probabilidad y que está estrechamente relacionado con el Criterio de Información de Akaike (AIC).. Cuando el ajuste de modelos, es posible ... The problem of selecting one of a number of models of different dimensions is treated by finding its Bayes solution, and evaluating the leading terms of its asymptotic expansion. These terms are a valid large-sample criterion beyond the Bayesian context, since they do not depend on the a priori distribution. 赤池信息准则（Akaike Information Criterion，AIC） AIC是衡量统计模型拟合优良性的一种标准，由日本统计学家赤池弘次在1974年提出，它建立在熵的概念上，提供了权衡估计模型复杂度和拟合数据优良性的标准。 通常情况下，AIC计算公式为： k是模型参数个数， L是似 ... Deshalb empfiehlt sich die Verwendung des durch Gideon Schwarz 1978 vorgeschlagenen bayesschen Informationskriteriums, auch Bayes-Informationskriterium, bayesianisches Informationskriterium, oder Schwarz-Bayes-Informationskriterium (kurz: SBC) genannt (englisch Bayesian Information Criterion, kurz: BIC). Akaike's Information Criteria was formed in 1973 and Bayesian Information Criteria in 1978. Hirotsugu Akaike developed Akaike's Information Criteria whereas Gideon E. Schwarz developed Bayesian information criterion. The AIC can be termed as a measure of the goodness of fit of any estimated statistical model. The history of scientific method considers changes in the methodology of scientific inquiry, as distinct from the history of science itself. The development of rules for scientific reasoning has not been straightforward; scientific method has been the subject of intense and recurring debate throughout the history of science, and eminent natural philosophers and scientists have argued … Aug 15, 2020 · 赤池信息准则（Akaike Information Criterion，AIC）AIC是衡量统计模型拟合优良性的一种标准，由日本统计学家赤池弘次在 … 贝叶斯信息准则（Bayesian Information Criterion，BIC） BIC（Bayesian InformationCriterion）贝叶斯信息准则与AIC相似，用于模型选择，1978年由Schwarz提出。 Apr 07, 2019 · 赤池信息量准则(转) (2012-04-13 12:13:27) 转载 标签： 杂谈 赤池信息量准则（Akaike information criterion、简称AIC）是衡量统计模型拟合优良性的一种标准，是由日本统计学家赤池弘次创立和发展的。赤池信息量准则建立在熵的概念基础上，可以权衡所估计模型的复杂度和此模型拟合数据的优良性。 In statistics, the Bayesian information criterion (BIC) or Schwarz information criterion (also SIC, SBC, SBIC) is a criterion for model selection among a finite set of models; models with lower BIC are generally preferred. It is based, in part, on the likelihood function and it is closely related to the Akaike information criterion (AIC).. When fitting models, it is possible to increase the ... In several sections of the book the reader will find these objections clearly stated. DSM-IV is a diagnostic and statistical manual; it is not and never claimed to be a textbook. Unfortunately, it is used as a text by some groups, including insurance companies who believe it to be a comprehensive source of information about mental illness. We are now going to choose the best-fitting models according to Akaike Information Criterion (AIC) (Akaike 1974), Akaike Information Criterion corrected for small sample sizes (AICc) (Hurvich and Tsai 1989), Bayesian Information Criterion (BIC) (Schwarz 1978), and a decision-theoretic performance-based approach (DT) (Minin et al. 2003). Go back ... Bayesian probability is an interpretation of the concept of probability, in which, instead of frequency or propensity of some phenomenon, probability is interpreted as reasonable expectation representing a state of knowledge or as
